

Domestic optical power meters are inaccurate

Overview

A power meter is only as accurate as the technician using it. Skipped reference, wrong wavelength, dirty connector, or a wrong-direction measurement will give you confidently incorrect readings every time. Its sole function is to measure the optical power level arriving at a specific point in a fiber link, expressed in dBm or mW. At its core, the device consists of: The power meter does not evaluate. Systematic uncertainties are errors that are an intrinsic and constant part of the process and can be quantified or estimated from a simple measurement. This guide walks through the full procedure -- from cleaning the connector to interpreting. NIST has established measurement services for the calibration of optical fiber power meters at the three nominal wavelengths of 850, 1300, and 1550 nm using either collimated beam or optical fiber/connector configurations. Consistent procedures ensure accuracy. Verify light travels from transmitter to receiver. These inaccuracies can result in consumers being overcharged or undercharged for their electricity consumption.
